Researchers at the University of Granada have discovered a compound in olives that can help in preventing cancer.

Maslinic acid is a compound present in the leaf and the olive skin wax extracted from alpeorujo (crushed olive pulp) that can regulate cancer cell growth and prevents their appearance.

The [acid controls](#) the hyperplasia, proliferation of cells within an organ or tissue and hypertrophy, the increase of the size of an organ or in a select area of the tissue, typical of this disease.

According to lead researchers Professor Jose Antonio Lupianez Cara, of the department of Biochemistry and Molecular Biology I and Ph D student Fernando Jesus Reyes Zurita, unlike other anti-carcinogenic products, maslinic acid is a natural compound, thus is less toxic. In addition it only acts on carcinogenic cells, whose pH is more acid than usual and can inhibit cancer appearance in those cells with a higher
