An efficient response in primary care would reduce the use of hospitals by elderly people and hospitalisation costs

10.03.2008 > nächste Meldung >

Researchers from the Department of Preventive Medicine and Public Health from the University of Granada have carried out a study with patients over 60. The main conclusion they have come to is that an efficient response in primary care would reduce hospitalisations in more than 50% of the cases caused by three of the most frequent pathologies in older population: diabetic ketoacidosis, digestive haemorrhage and chronic bronchitis.

The study, carried out by Doctor Isabel Valenzuela López and supervised by Professors Aurora Bueno Cavaillas and José Luis Gastón Morata, has analysed the main reasons for hospitalisations caused by the pathologies that demand an effective response in primary care and how these hospitalisations could be avoided.

40-50% of doctors working in primary care, and is the recipient of more than 50% of the medicines prescribed in hospitals.

The researchers interviewed all the family doctors from seven different hospitals in Granada and asked them about the main reasons for hospitalisations in patients over 60 as well as to what extent these hospitalisations, caused by the problems described above, could be prevented. The interviewed professionals answered that a more efficient response in primary health care would reduce in more than 50% the hospitalisations caused by three pathologies: diabetic ketoacidosis, digestive haemorrhage and chronic bronchitis. However, in patients suffering from cancer and acute coronary syndrome an enhanced primary care would only reduce the hospitalisations by 25%.

Scientists analysed 6 health problems, 3 chronic diseases (acute coronary syndrome, chronic bronchitis and diabetes) and three acute ones (pneumonia, transient ischemic attack and digestive haemorrhage) to find the connection

by these health problems. 717 patients over 60 were taken for the study, with an average age of 75.65 years 59.97% of whom were men.

Twice the risk

Isabel Valenzuela outlines that, according to the study, "each new chronic disease suffered by a patient means twice the risk of hospitalisation by any of the 6 studied pathologies" which means that anyone suffering 5 or more diseases would present a probability of hospitalisation 61 times higher than someone healthy. Moreover, each new medicine prescribed increases the risk of hospitalisation. Those patients who have been taking 5 or more different medications for the last 6 months have a 4.84 times increase in their risk of hospitalisation for these pathologies.

In short, the number of pathologies suffered by individual as well as past hospitalisations for causes different to those studied was considered as a risk factor for hospitalisations, although more significantly for severe cases. The amount of medicines consumed and the number of visits to the hospital was related with a higher frequency of hospitalisation, especially in chronic cases.

Part of the results from this study has been published in the prestigious journal "Atención Primaria". Furthermore, manuscripts will widely spread the significant results in specialized journals.
